# 1 What is LaTeX

So you decided to get started with LaTeX. Great! So let's talk a bit about the basic concept and differences it comes with.

Up to this point you probably used a Word Processor like MS Word. The kind of workflow you know from there is often referred to as *What you see is what you get*. You see the exact final layout as you type it, press some colourful buttons to insert stuff and if it doesn't want to do something you need, you're screwed.

LaTeX on the other hand falls into the category of *What you see is what you mean*, which describes all forms of markup languages. This means you create your LaTeX document as a simple plain text file without any form of formatting and mix in a bunch of commands telling what you mean. For example: "This is supposed to be a chapter heading", "make this bold" or "insert an image here". This source file will then be passed to a document processor (the LaTeX program), which will, depending on its settings, create the document for you. The advantage is, that you can use the same markup with all sorts of formatings and target file types.

This is why working with LaTeX will require some getting used to and you will find yourself wanting to compile every five seconds to see the document update. Try to restrain yourself and concentrate on writing. You will find yourself working much faster.

## 1.1 Following this document

To see how the LaTeX source code and the resulting PDF correspond, I recommend you open this document's source code and PDF file next to each other and scroll through them simultaneously.

If you already have a working LaTeX setup, most editors support *SyncTex*, which allows you to jump between source code and PDF file and vice versa. You have to compile yourself, which will create a file called `example.synctex.gz` in your project directory. Now you can `<CTRL>+Click` in the PDF and the corresponding line of source code will be highlighted.

The shortcut to jump from the source code into the PDF will depend on your Editor, but for VS Code it's right `Click`→`SyncTex` from cursor or `CTRL+ALT+J`.

## 1.2 Requirements to use LaTeX

As LaTeX files are just plain text files, you can edit them with any text editor (even Windows Notepad works, but that's just terrible). However, I would strongly recommend a more suitable editor. I use Visual Studio Code (which is a multi-purpose text editor that supports all major programming languages) but you could also use something like Texmaker, which is an editor specifically for LaTeX. There is also the online editor Overleaf, which saves you the trouble of setting up your own LaTeX installation and provides everything you need in the cloud.

As I have already mention above, you also need the LaTeX program. It comes bundled with packages and other additional software inside a Tex-distribution. There are two major ones, Texlive and MiKTeX. I recommend MiKTeX, but it essentially doesn't matter which one you choose.

Once you have the distribution installed, test it by running `pdflatex --version` in any terminal windows and it should return you some information about the installed version and setup.

## 1.3 Running LaTeX

To create a PDF file from your LaTeX source code, you can always navigate to the project folder in a terminal window and run `pdflatex filename.tex`. However, if you have a decent editor installed, it will provide you with a button and do this for you.

With these project files you also received a makefile, which demonstrates how to compile this example file successfully from the terminal. The README file also has some tips and information for you.

If you use VS Code, this project also contains settings for LaTeX and recommended extensions. If you open the folder for the first time you will be asked if you want to install them and should than be able to compile this file.

## 1.4 LaTeX commands

Now lets look at the LaTeX command. Every one will begin with a `\` followed by a letters only command name, like this: `\command`. Most commands also accept input, which is put after it into curly brackets: `\command{argument}`. They can accept multiple arguments either in multiple sets of curly brackets or as a comma separated list, depending on the command.

Some commands also accept optional arguments. These are passed inside square brackets between the command name and the curly brackets, like this: `\command[optional]{argument}`.

## 1.5 Getting more information

So what can you do if you get stuck or just want more information. The simple answer is: Google is your friend. Most questions have already been answered. For example on [Tex Strackexchange](#). Also, Overleaf has a great section for learning LaTeX.

An of course you can always check the documentation, which you can find on CTAN.
